

Your Project Title

A one-line statement of what it is

Team Member One Team Member Two

October 5, 2026

Context

What this is

Name the topic and say plainly what it is, in one paragraph, before any argument about why it matters. A reader who stops here should be able to describe the thing correctly to someone else, even if coarsely.

Define it in terms of what it does, not what it is built from. Resist the urge to justify it — that is the next section's job, and mixing the two is the most common way a tutorial loses its opening.

Replace this paragraph.

Where it came from

The short history: what problem it was invented to solve, by whom or in what setting, and what people did before it existed.

This is not a literature survey and not a timeline. Two or three sentences of origin earn their place because they explain the design — most of what looks arbitrary about a tool is a fossil of the problem it was built for. Cut any history that does not explain something the reader will meet later.

Replace this paragraph.

What this tutorial covers

The scope and the roadmap. Name each section and what the reader gets from it, and say what the reader will be able to do by the end — a capability, not a list of topics.

Say what is out of scope here too. This is the promise the rest of the tutorial must keep, and the panel will check it against what you actually delivered.

Replace this paragraph.

Motivation

Why it matters for agentic development

The case, made concretely. What does this tool, technique, or notion let an agentic system do that is hard or impossible without it?

Tie it to agentic development specifically — not to software in general. If the answer would read the same for any programming topic, you have not made the case yet.

Replace this paragraph.

What goes wrong without it

The failure it prevents, shown rather than asserted. A concrete situation that goes badly, and how it goes badly.

This is the paragraph that makes the tutorial worth reading. A reader who has felt the failure will follow you through the mechanics; one who has not will skim. Use a real case if you have one.

Replace this paragraph.

When to reach for it

The bounds, stated by you rather than discovered by a frustrated reader. What it is good for, and — just as important — when it is the wrong tool. A technique with honestly stated limits is more usable than one presented as universal, because the reader can tell whether their situation is in scope.

Replace this paragraph.

Content

How it works

The mental model, before any procedure. What are the moving parts and how do they relate? A reader who has this can predict what the tool will do in a case you never showed them; one who has only the steps cannot.

This is the unit most likely to need a figure — the boxes, the arrows, the one relationship the prose leaves abstract. See `figures/README.md`.

Replace this paragraph.

Using it: the basic case

The first walkthrough, concrete enough to follow along. Show the actual commands, code, or configuration — not a description of them.

Pick the smallest case that is still real. A toy that could not occur in practice teaches the toy; a realistic case teaches the tool.

Replace this paragraph.

Using it: going further

The second case, one step harder, chosen to expose something the first one hid. Say what is new here and why the basic case could not show it.

Split this into several ## units if it does not fit one slide. That split is a feature: it forces you to find the joints in your own explanation.

Replace this paragraph.

Pitfalls

The mistakes people actually make, and what each one looks like when it happens. Lead with the symptom the reader will see, then the cause. Prefer the errors you have made yourself. Invented pitfalls are obvious to a reader who has made the real ones.

Replace this paragraph.

Examples

A complete worked example

One end-to-end case, start to finish, with the actual input and the actual output. Where § Content showed a step at a time, this shows the whole thing at once, so the reader sees how the parts compose.

Choose a case a reader could plausibly meet on their own. The point is not to impress; it is to let the reader check their mental model against a run they can follow in full.

Replace this paragraph.

An example that breaks the simple story

A case where the obvious approach fails or does something surprising, and what the tool does instead. Say up front what makes it different from the complete example.

This is where the reader learns the bounds from the inside. A tutorial that only shows successes leaves the reader to discover the edges alone.

Replace this paragraph.

What the examples have in common

The pattern the cases share, stated once. If a reader remembered only this slide, what would they carry to a case you never showed them?

Keep it to what the examples actually demonstrated. Anything here that none of them showed belongs back in § Content, or nowhere.

Replace this paragraph.

Conclusion

What you can do now

The recap, stated as capability rather than as summary. Not “we covered X” — rather, what the reader can now do that they could not before.

Keep it to what the tutorial actually delivered. This paragraph and § What this tutorial covers must agree exactly; the panel will check.

Replace this paragraph.

Where to go next

The next thing to learn, and why it is the next one. Name the specific resource, tool, or topic and say what it adds.

Order matters more than length. Three pointers in a sensible sequence beat a list of ten a reader has to triage themselves.

Replace this paragraph.

What is still unsettled — where the tool is changing, where practice has not converged, where you would not yet give firm advice.

End on the opening you leave, not on a restatement. A tutorial that admits its edges is more trustworthy than one that implies the topic is finished.

Replace this paragraph.
